Assignment 4 (WQUC)

Start Assignment

Due Monday by 11:59pm Points: 10 Submitting a website or a file upload Available On 8 at 8am - On 11 at 11:59pm

Your task is

Step 1:

Implement helper-weighted Quicksort with P -Bit Compression. For this, you will find out the class `WQUC`. All you have to do is to fix in the section marked with P BIT IMPLEMENTATION.

OR

OR Check that the unit tests for this class are ok. You must show "green" test results in your submission screenshot is OK.

Step 2:

Using your implementation of `WQUC`, develop a `WQUC` function that takes an integer value n from the keyboard to determine the number of "wins". Then generate random pairs of integers between 1 and n , calling `WQUC` to determine if they are connected and output `WQUC`. Your code must also use connected flow print the number of connections generated. Package your program in a static method `countWins` in the class `WQUC` and return the number of connections, and a matrix that takes from the class `WQUC` and prints the returned value. From here, you can create a main program that doesn't require any input and run the experiment for a fixed set of values. (Show evidence of your work).

Step 3:

Determine the relationship between the number of objects in `WQUC` and the number of pairs in `WQUC` to accomplish this. Is to reduce the number of components from n to 1. Justify your conclusion in terms of your observations and what you think might be going on.

NOTE: Although I'm not going to tell you in advance what the `WQUC` is, I can assure you that it is a simple relationship.

Assignment 4 (WQUPC)

Due: Monday by 11:59pm
Points: 50
Available: Oct 8 at 8am - Oct 21 at 11:59pm

Submitting: a website url or a file upload

Your task is:

Step 1:

(a) Implement height-weighted Quick Union with Path Compression. For this, you will flesh out the class UF_HWQUPC. All you have to do is to fill in the sections marked with `// TO BE IMPLEMENTED` ... `// END IMPLEMENTATION`.

(b) Check that the unit tests for this class all work. You must show "green" test results in your submission (screenshot is OK).

Step 2:

Using your implementation of UF_HWQUPC, develop a UF ("union-find") client that takes an integer value n from the command line to determine the number of "sites." Then generates random pairs of integers between 0 and $n-1$, calling `uf.union(i, j)` to determine if they are connected and `uf.connected(i, j)` if not. Loop until all sites are connected then print the number of connections generated. Package your program as a static method `count()` that takes n as the argument and returns the number of connections; and a `main()` that takes n from the command line, calls `count()` and prints the returned value. If you prefer, you can create a main program that doesn't require any input and runs the experiment for a fixed set of n values. Show evidence of your run(s).

Step 3:

Determine the relationship between the number of objects (n) and the number of pairs (m) generated to accomplish this. Use to reduce the number of components from n to 1. Justify your conclusion in terms of your observations and what you think might be going on.

NOTE: although I'm not going to tell you in advance, this is a very simple problem. Be sure you that it is a simple relationship.
